

Percentage of Persons Without Health Insurance

Source: U.S. Bureau of the Census, Small Area Health Insurance Estimates (SAHIE) program.

Definition: This is an estimate of the percent of the population without health insurance, derived from a statistical model.

Limitations: Estimates exclude all persons living in military families and the population residing in institutional group quarters. Some examples of institutional group quarters are correctional facilities, juvenile institutions, and nursing homes. These estimates are produced from a statistical model – they were not directly measured. Consequently, the estimates contain an unknown amount of error.

Data Detail: Health insurance coverage estimates are made using statistical modeling techniques. The data are estimated from several symptomatic indicators, including the ratio of family income to the appropriate poverty ratios, Medicaid program participants under age 18 and age 35–64, the population receiving food stamps, Hispanic origin population, American Indian or Alaska Native population, and persons age 65 and over.
